DATA STRUCTURES & ALGORITHMS PROGRAMMING LAB

Prepared by:

Name of Student : Srivathsav Kyatham

Roll No: 01

Batch: 2023-27

Dept. of CSE

DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

INSTITUTE OF TECHNOLOGY AND MANAGEMENT
SKILLS UNIVERSITY,
KHARGHAR, NAVI MUMBAI

CERTIFICATE

This is to certify that Mr. / Ms. _____

Roll No. _____ Semester _____ of B.Tech Computer Science & Engineering, ITM Skills University, Kharghar, Navi Mumbai, has completed the term work satisfactorily in subject _____ for the academic year 20__ - 20__ as prescribed in the curriculum.

Place: _____

Date: _____

Subject I/C HOD

Exp. No	List of Experiment	Date of Submission	Sign
1	Implement Array and write a menu driven program to perform all the operation on array elements		

2	Implement Stack ADT using array.		
3	Convert an Infix expression to Postfix expression using stack ADT.		
4	Evaluate Postfix Expression using Stack ADT.		
5	Implement Linear Queue ADT using array.		
6	Implement Circular Queue ADT using array.		
7	Implement Singly Linked List ADT.		
8	Implement Circular Linked List ADT.		
9	Implement Stack ADT using Linked List		
10	Implement Linear Queue ADT using Linked List		
11	Implement Binary Search Tree ADT using Linked List.		
12	Implement Graph Traversal techniques: a) Depth First Search b) Breadth First Search		
01	Implement Binary Search algorithm to search an element in an array		
14	Implement Bubble sort algorithm to sort elements of an array in ascending and descending order		

Name of Student: Srivathsav Kyatham

Roll Number: 01

Experiment No: 1

Title: Implement Array and write a menu driven program to perform all the operation on array elements

Theory: Array is a collection of elements of similar data types and has a fixed size. We can access an element of the array through its index. Indexing starts from 0 till n-1 (where n=size of array). An element can be inserted in the array by shifting all the elements of the array to the right and making space for the element. Similarly, to delete an element, we need to shift all the elements from the right of the deleted element to the left side in order to overwrite the deleted element. In order to search for an element, we need to traverse through the array and print the appropriate message if the element is found or not.

Code:

```
// menu driven array operations program - 1.display array 2.insert at beginning 3.insert at  
end 4.insert before an element 5.insert after an element 6.delete at beginning 7.delete at  
end 8.delete before an element 9.delete after an element 10.search an element  
11.number of elements  
#include <iostream>  
#include <algorithm>  
using namespace std;  
void displayArray(int &a, int arr[]) // function to display array  
and number of elements in array  
{  
int count = 0;  
cout << "Array: ";  
for (int i = 0; i < a; i++)  
{  
if (arr[i] != -1)  
{
```

```
cout << arr[i] << " ";
count++;
}
else
{
break;
}
}
cout << endl
<< "Number of elements: " << count << endl; }
void insertAtBegin(int &a, int arr[]) // function to insert element
at the beginning of the array
{
if (a >= 45)
{
cout << "Array is full. Cannot insert at the beginning." << endl;
return;
}
int b, count = 0;
cout << "Enter beginning detail: ";
cin >> b;
for (int i = a - 1; i >= 0; i--)
{
arr[i + 1] = arr[i];
}
arr[0] = b;
a++;

Title: Implement Stack ADT using Array.

Theory: Array is a collection of elements of similar data types and has a fixed size. We can access an element of the array through its index. Indexing starts from 0 till n-1 (where n=size of array).

Stack is an Abstract Data Type which can be implemented using Linked List or Array. It consists of a variable named Top which points to the topmost element of the stack. Stack follows LIFO principle (Last In, First Out) which means that the element which is inserted last will be deleted first. There are three operations in Stack: Push- insertion from top, Pop- deletion from top, Peek- returning the topmost element from the stack.

Code:

```
// stack operations(array)
#include <iostream>
using namespace std;

int main()
{
    int top = -1, element, op, n;
    cout << "Enter size of stack: ";
    cin >> n;
    int stack[n];
    while (true)
    {
        cout << "\nStack operation\n";
        cout << "1.Push\n2.Pop\n3.Peek\n4.Exit\n";
        op = 0;
        while (op < 4)
        {
            op = 1;
            break;
        }
        switch (op)
        {
            case 1:
                element = 0;
                while (element < n)
                {
                    element++;
                }
                stack[top] = element;
                top++;
                break;
            case 2:
                if (top > -1)
                {
                    top--;
                }
                break;
            case 3:
                if (top > -1)
                {
                    cout << "Top element is: " << stack[top] << "\n";
                }
                break;
            case 4:
                return 0;
        }
    }
}
```

```

cin >> op;
switch (op)
{
case 1:
if (top == n - 1)

cout << "Stack is full. Cannot add more elements.\n";
break;

else

cout << "Enter element: ";
cin >> element;
top++;
stack[top] = element;
cout << "Element added in stack\n"; }
break;
case 2:
if (top == -1)

Title: Convert an Infix expression to Postfix expression using Stack ADT.

Theory: Stack is an Abstract Data Type which can be implemented using Linked List or Array. It consists of a variable named Top which points to the topmost element of the stack. Stack follows LIFO principle (Last In, First Out) which means that the element which is inserted last will be deleted first. There are three operations in Stack: Push- insertion from top, Pop- deletion from top, Peek returning the topmost element from the stack. Using stack, we can convert an infix expression to postfix expression by pushing the operators and brackets in the stack and the operands to the expression and popping the elements to the expression through operator precedence after encountering a closing bracket.

Code:

```
// conversion of infix to postfix expression using stack(array)
#include <iostream>
using namespace std;

int precedence(char op)
{
    if (op == '+' || op == '-')
    {
        return 1;
    }
    else if (op == '*' || op == '/' || op == '%')
    {
        return 2;
    }
}
```

```

    else
    {
        return 0;
    }
}

int main()
{
    string exp, result = "";
    char stack[100];
    int top = -1;
    cout << "Enter infix expression: ";
    getline(cin, exp);
    int n = exp.length();
    char express[n + 2];
    express[0] = '(';
    for (int i = 0; i < n; i++)
    {
        express[i + 1] =
            exp[i];
    }
    express[n + 1] = ')';
    for (int i = 0; i < n + 2; i++)
    {
        if (express[i] == '(')
        {
            top++;
            stack[top] =
                express[i];
        }
        else if (express[i] == ')')
        {
            while (stack[top] != '(' && top > -1)
            {
                result += stack[top];
                top--;
            }
            top--;

            else if ((express[i] >= 'a' && express[i] <= 'z') || (express[i] >= 'A' && express[i] <= 'Z') ||
                (express[i] >= '0' && express[i] <= '9'))
            {
                result +=
                    express[i];
            }
            else
            {
                while (top > -1 && precedence(stack[top]) >= precedence(express[i]))
                {
                    result += stack[top];
                    top--;
                }
                top++;
                stack[top] =
                    express[i];
            }
        }
    }
}

```

```

Stack follows LIFO principle (Last In, First Out) which means that the element which is inserted last will be deleted first. There are three operations in Stack: Push- insertion from top, Pop- deletion from top, Peek returning the topmost element from the stack. Using stack, we can evaluate a postfix expression by pushing the operands in the stack and popping them and evaluating them when an operator is encountered and popping the result back in the stack and printing the topmost element after the whole expression is evaluated.

Code:

```
// evaluating postfix expression using stack(array)
#include <iostream>

using namespace std;

// Stack implementation

class Stack {

private:

    int top;

    int *arr;

    int capacity;

public:

    Stack(int size) {
```

```
        capacity = size;
        arr = new int[size];
        top = -1;
    }

    ~Stack() {
        delete[] arr;
    }

    void push(int data) {
        if (isFull()) {
            cout << "Stack Overflow!" << endl;
            return;
        }
        arr[++top] = data;
    }

    int pop() {
        if (isEmpty()) {
            cout << "Stack Underflow!" <<
endl;
            return -1;
        }
        return arr[top--];
    }

    int peek() {
```

```

        if (isEmpty()) {
            cout << "Stack is empty!" << endl;
            return -1;
        }
        return arr[top];
    }

    bool isEmpty() {
        return top == -1;
    }

    bool isFull() {
        return top == capacity - 1;
    }
};

int evaluatePostfix(char* expression) {
    Stack operandStack(100);
    for (int i = 0; expression[i]; ++i) {
        if (isdigit(expression[i])) {
            operandStack.push(expression[i] -
'0');

Title: Implement Circular Queue ADT using array.

Theory: Array is a collection of elements of similar data types and has a fixed size. We can access an element of the array through its index. Indexing starts from 0 till n-1 (where n=size of array).

Queue is an Abstract Data Type which can be implemented using Linked List or Array. It consists of two variables named Front and Rear which point to the first and last elements of the queue, respectively. Queue follows FIFO principle (First In, First Out) which means that the element which is inserted first will be deleted first. There are three operations in Queue: Enqueue- insertion from rear, Dequeue- deletion from front, Peek- returning the frontmost element from the queue. As size of array is fixed, in order to overcome the challenges, we can move the rear pointer to the start of the array if rear=n-1 and front is not at first index, so we can continue to insert elements.

Code:

```
// circular queue menu driven operations(array)
#include <iostream>
using namespace std;
const int MAX_SIZE = 100;
class CircularQueue
{ private:
    int front, rear;
    int arr[MAX_SIZE];
public:
    CircularQueue() {
        front = -1;
        rear = -1;
    }
    bool isEmpty() {
```

```

        return front == -1;
    }

    bool isFull() {
        return (front == 0 && rear == MAX_SIZE - 1) || (rear ==
front - 1);
    }

    void enqueue(int data) {
        if (isFull()) {
            cout << "Queue is full. Cannot enqueue." << endl;
            return;
        }
        if (isEmpty()) {
            front = 0;
        }
        rear = (rear + 1) % MAX_SIZE;
        arr[rear] = data;
        cout << data << " enqueued to queue." << endl;
    }

    void dequeue() {
        if (isEmpty()) {
            cout << "Queue is empty. Cannot dequeue." << endl;
            return;
        }
        int data = arr[front];
        if (front == rear) {
            front = rear = -1;
        } else {
            front = (front + 1) % MAX_SIZE;
        }
        cout << data << " dequeued from queue." << endl;
    }
}

```

```

int peek() {
    if (isEmpty()) {
        cout << "Queue is empty. Cannot peek." << endl;
        return -1;
    }
    return arr[front];
}

void display() {
    if (isEmpty()) {
        cout << "Queue is empty." << endl;
        return;
    }
    cout << "Queue elements: ";
    int i = front;
    while (i != rear) {
        cout << arr[i] << " ";
        i = (i + 1) % MAX_SIZE;
    }
    cout << arr[rear] << endl;
}

};

int main()
{ CircularQueue
q; int choice,
data; do {
    cout << "\n1. Enqueue\n2. Dequeue\n3. Peek\n4. Display\n5.
Exit\n";
    cout << "Enter your choice: ";
    cin >> choice;
    switch (choice) {
        case 1:

```

```

        cout << "Enter data to enqueue: ";
        cin >> data;
        q.enqueue(data);
        break;

    case 2:
        q.dequeue();
        break;

    case 3:
        cout << "Front element: " << q.peek() << endl;
        break;

    case 4:
        q.display();
        break;

    case 5:
        cout << "Exiting program." << endl;
        break;

    default:
        cout << "Invalid choice. Please enter a valid
option." << endl;
        break;
    }
} while (choice != 5);
return 0;
}

```

Output: (screenshot)

```

1. Enqueue
2. Dequeue
3. Peek
4. Display
5. Exit
Enter your choice: 1
Enter data to enqueue: 234
234 enqueued to queue.

1. Enqueue
2. Dequeue
3. Peek
4. Display
5. Exit
Enter your choice: 1
Enter data to enqueue: 7654
7654 enqueued to queue.

1. Enqueue

```

Conclusion: Therefore, using array, we can implement a circular queue and perform operations like Enqueue, Dequeue and Peek without being constrained by the limitation of the fixed size of the array.

Title: Implement Singly Linked List ADT.

Theory: Linked List is a data type which consists of nodes which contain data and a next pointer which points to the next node in the list. It stores the address of the next node. There is a start pointer in stack memory which points to the first node in the heap memory. It utilises dynamic memory and allocates heap memory to the nodes in the list. The last node's next pointer has NULL value to indicate it's the last node in the list.

Code:

```
// menu driven linked list
#include <iostream>
using namespace std;
class Node {
public:
    int data;
    Node* next;
    Node(int value)
    { data = value;
      next = nullptr;
    }
};
class SinglyLinkedList
{ private:
    Node* head;
public:
    SinglyLinkedList() {
        head = nullptr;
    }
};
```

```

    }

    void insertAtBeginning(int value)
    { Node* newNode = new
      Node(value); newNode->next =
        head;
      head = newNode;
    }

    void insertAtEnd(int value) {
      Node* newNode = new Node(value);
      if (head == nullptr) {
        head = newNode;
        return;
      }
      Node* temp = head;
      while (temp->next != nullptr) {
        temp = temp->next;
      }
      temp->next = newNode;
    }

    void display() {
      Node* temp = head;
      while (temp != nullptr) {
        cout << temp->data << " ";
        temp = temp->next;
      }
      cout << endl;
    }

    ~SinglyLinkedList() {
      Node* temp = head;
      while (head != nullptr)
        { head = head->next;

```

```

        temp = head;
    }
}

};

int main()
{
    SinglyLinkedList
    list; int choice,
    value;

    do {
        cout << "\n1. Insert at Beginning\n2. Insert at End\n3.
Display\n4. Exit\n";
        cout << "Enter your choice: ";
        cin >> choice;
        switch (choice) {
            case 1:
                cout << "Enter value to insert at the beginning: ";
                cin >> value;
                list.insertAtBeginning(value);
                break;
            case 2:
                cout << "Enter value to insert at the end: ";
                cin >> value;
                list.insertAtEnd(value);
                break;
            case 3:
                cout << "Linked List elements: ";
                list.display();
                break;
            case 4:
                cout << "Exiting program." << endl;
                break;
        }
    } while (choice != 4);
}

```

```

        cout << "Invalid choice. Please enter a valid
option." << endl;
        break;
    }
    } while (choice != 4);
    return 0;
}

```

Title: Implement Circular Linked List ADT.

Theory: Linked List is a data type which consists of nodes which contain data and a next pointer which points to the next node in the list. It stores the address of the next node. There is a start pointer in stack memory which points to the first node in the heap memory. It utilises dynamic memory and allocates heap memory to the nodes in the list. The last node's next pointer has the address of first node, hence it's called circular linked list.

Code:

```
// circular linked list menu

#include <iostream>

using namespace std;

class Node {
public:
    int data;

    Node* next;

    Node(int value)
    { data = value;
      next = nullptr;
    }
};

class CircularLinkedList
{ private:
```

```

Node* head;

public:

CircularLinkedList() {

    head = nullptr;

}

void insertAtBeginning(int value)

{ Node* newNode = new

Node(value); if (head ==

nullptr) {

    newNode->next = newNode; // Point to itself

    head = newNode;

    return;

}

Node* temp = head;

while (temp->next != head) {

    temp = temp->next;

}

temp->next = newNode;

newNode->next = head;

head = newNode;

}

void insertAtEnd(int value) {

    Node* newNode = new Node(value);

```

```

        newNode->next = newNode; // Point to itself

        head = newNode;

        return;
    }

    Node* temp = head;
    while (temp->next != head) {
        temp = temp->next;
    }

    temp->next = newNode;
    newNode->next = head;
}

void display() {
    if (head == nullptr) {
        cout << "Circular Linked List is empty" << endl;
        return;
    }

    Node* temp = head;
    do {
        cout << temp->data << " ";
        temp = temp->next;
    } while (temp != head);

    cout << endl;
}

```

```

~CircularLinkedList() {
    if (head == nullptr) return;

    Node* temp = head;

    while (temp->next != head)
    {
        Node* toDelete = temp;

        temp = temp->next;

        delete toDelete;
    }

    delete temp;
}

};

int main()
{
    CircularLinkedList
    list; int choice, value;

Title: Implement Stack ADT using Linked List.

Theory: Stack is an Abstract Data Type which can be implemented using Linked List or Array. It consists of a variable named Top which points to the topmost element of the stack. Stack follows LIFO principle (Last In, First Out) which means that the element which is inserted last will be deleted first. There are three operations in Stack: Push- insertion from top, Pop- deletion from top, Peek returning the topmost element from the stack. We can implement insertion at beginning, deletion from beginning algorithms to implement Stack using Linked List.

Linked List is a data type which consists of nodes which contain data and a next pointer which points to the next node in the list. It stores the address of the next node. There is a start pointer in stack memory which points to the first node in the heap memory. It utilises dynamic memory and allocates heap memory to the nodes in the list. The last node's next pointer has the address of first node, hence it's called circular linked list.

Code:

```
// stack operations(linked list)

#include <iostream>

using namespace std;

class Node {
public:
    int data;

    Node* next;

    Node(int value) {
        data = value;
    }
};
```

```

        next = nullptr;

    }

};

class Stack {
private:
    Node* top;
public:
    Stack() {
        top = nullptr;
    }

    void push(int value) {
        Node* newNode = new Node(value);
        newNode->next = top;
        top = newNode;
    }

    int pop() {
        if (isEmpty()) {
            cout << "Stack is empty. Cannot pop." << endl;
            return -1; // Return some invalid value
        }

        int poppedValue = top->data;
        Node* temp = top;
        top = top->next;
    }
};

```

```

        delete temp;

        return poppedValue;
    }

    int peek() {
        if (isEmpty()) {
            cout << "Stack is empty. Cannot peek." << endl;

            return -1; // Return some invalid value
        }

        return top->data;
    }

    bool isEmpty() {
        return top == nullptr;
    }

    ~Stack() {
        while (!isEmpty()) {
            pop();
        }
    }
};

int main() {
    Stack stack;

    int choice, value;

    do {

```

```
cout << "\n1. Push\n2. Pop\n3. Peek\n4. Exit\n";

cout << "Enter your choice: ";

cin >> choice;

switch (choice) {

    case 1:

        cout << "Enter value to push: ";

        cin >> value;

        stack.push(value);

        break;

    case 2:

        cout << "Popped value: " << stack.pop() << endl;

        break;

    case 3:

        cout << "Top of stack value: " << stack.peek() <<
endl;

        break;

    case 4:

        cout << "Exiting program." << endl;

        break;

    default:

        cout << "Invalid choice. Please enter a valid
option." << endl;

        break;
```

```
    }  
  
    } while (choice != 4);  
  
    return 0;  
}
```

Output: (screenshot)

```
1. Push  
2. Pop  
3. Peek  
4. Exit  
Enter your choice: 1  
Enter value to push: 23  
  
1. Push  
2. Pop  
3. Peek  
4. Exit  
Enter your choice: 1  
Enter value to push: 2  
  
1. Push  
2. Pop  
3. Peek  
4. Exit  
Enter your choice: 1  
Enter value to push: 23  
  
1. Push  
2. Pop  
3. Peek  
4. Exit  
Enter your choice: 1  
Enter value to push: 567  
  
1. Push  
2. Pop  
3. Peek  
4. Exit  
Enter your choice: 4  
Exiting program.
```

Test Case: Any two (screenshot)

```
1. Push
2. Pop
3. Peek
4. Exit
Enter your choice: 2
Popped value: 23

1. Push
2. Pop
3. Peek
4. Exit
Enter your choice: 2
Popped value: 234

1. Push
2. Pop
3. Peek
4. Exit
Enter your choice: 2
Popped value: 23

1. Push
2. Pop
3. Peek
4. Exit
Enter your choice: 2
Popped value: Stack is empty. Cannot pop.
-1
```

Conclusion: Therefore, we can implement Stack by linked list by using class or structure and allocate heap memory for the node by using new operator or malloc function. We can deallocate memory for the node by using free function or delete operator. We can implement push and pop operations through insertion at beginning and deletion from beginning algorithms.

Title: Implement Linear Queue ADT using Linked List.

Theory: Queue is an Abstract Data Type which can be implemented using Linked List or Array. It consists of two variables named Front and Rear which point to the first and last elements of the stack, respectively. Queue follows FIFO principle(First In, First Out) which means that the element which is inserted first will be deleted first. There are three operations in Stack: Enqueue- insertion from rear, Dequeue- deletion from front, Peek- returning the frontmost element from the queue. It can be implemented by insertion at end and deletion from beginning algorithms.

Linked List is a data type which consists of nodes which contain data and a next pointer which points to the next node in the list. It stores the address of the next node. There is a start pointer in stack memory which points to the first node in the heap memory. It utilises dynamic memory and allocates heap memory to the nodes in the list. The last node's next pointer has the address of first node, hence it's called circular linked list.

Code:

```
// queue menu driven program(linked list)
```

```
#include <iostream>
using namespace std;
class Node {
public:
    int data;
    Node* next;
    Node(int value)
    { data = value;
      next = nullptr;
    }
};
```

```
class Queue {
private:
    Node* front;
    Node* rear;
public:
    Queue() {
        front = nullptr;
        rear = nullptr;
    }
    void enqueue(int value) {
        Node* newNode = new Node(value);
        if (isEmpty()) {
            front = rear =
newNode; } else {
            rear->next = newNode;
            rear = newNode;
        }
        cout << value << " enqueued to queue." << endl;
    }
    int dequeue() {
        if (isEmpty()) {
            cout << "Queue is empty. Cannot dequeue." << endl;
            return -1; // Return some invalid value
        }
        int dequeuedValue = front->data;
        Node* temp = front;
        if (front == rear) {
            front = rear =
nullptr; } else {
            front = front->next;
        }
    }
}
```

```

        delete temp;
        return dequeuedValue;
    }
    int peek() {
        if (isEmpty()) {
            cout << "Queue is empty. Cannot peek." << endl;
            return -1; // Return some invalid value
        }
        return front->data;
    }
    bool isEmpty() {
        return front == nullptr;
    }
    ~Queue() {
        while (!isEmpty()) {
            dequeue();
        }
    }
};

int main() {
    Queue queue;
    int choice, value;
    do {
        cout << "\n1. Enqueue\n2. Dequeue\n3. Peek\n4. Exit\n";
        cout << "Enter your choice: ";
        cin >> choice;
        switch (choice) {
            case 1:
                cout << "Enter value to enqueue: ";
                cin >> value;
                queue.enqueue(value);

```

```

        break;
    case 2:
        cout << "Dequeued value: " << queue.dequeue() <<
endl;
        break;
    case 3:
        cout << "Front of queue value: " << queue.peek() <<
endl;
        break;
    case 4:
        cout << "Exiting program." << endl;
        break;
    default:
        cout << "Invalid choice. Please enter a valid
option." << endl;
        break;
    }
} while (choice != 4);
return 0;
}

```

Output: (screenshot)

```

1. Enqueue
2. Dequeue
3. Peek
4. Exit
Enter your choice: 1
Enter value to enqueue: 334
334 enqueued to queue.

1. Enqueue
2. Dequeue
3. Peek
4. Exit
Enter your choice: 1
Enter value to enqueue: 3456
3456 enqueued to queue.

1. Enqueue
2. Dequeue
3. Peek
4. Exit
Enter your choice: 4
Exiting program.

```

Conclusion: Therefore, we can implement Linear Queue by linked list by using class or structure and allocate heap memory for the node by using new operator or malloc function. We can deallocate memory for the node by using free function or delete operator. We can implement enqueue and dequeue operations through insertion at end and deletion from beginning algorithms.

Title: Implement Binary Search Tree ADT using Linked List.

Theory:

A binary tree is a non-linear data structure in which there is a root node and each parent node has 0,1 or 2 child nodes at most. In binary search tree, all the nodes having values less than that of the root node are present in the left subtree of the root node and all the nodes having values greater than or equal to that of the root node are present in the right subtree of the root node.

Code:

```
// Binary Search Tree using Linked List

#include <iostream>

using namespace std;

class TreeNode
{ public:

    int data;

    TreeNode* left;

    TreeNode* right;

    TreeNode(int value) {
```

```

        data = value;

        left = nullptr;

        right = nullptr;

    }

};

class BinarySearchTree
{ private:

    TreeNode* root;

    TreeNode* insertRecursively(TreeNode* root, int value) {

        if (root == nullptr) {

            return new TreeNode(value);

        }

        if (value < root->data) {

            root->left = insertRecursively(root->left, value);

        } else if (value > root->data) {

            root->right = insertRecursively(root->right, value);

        }

        return root;

    }

    void inorderTraversal(TreeNode* root) {

        if (root != nullptr)

            { inorderTraversal(root->

                left); cout << root->data <<

```

```

        inorderTraversal(root->right);

    }

}

public:

    BinarySearchTree() {

        root = nullptr;

    }

    void insert(int value) {

        root = insertRecursively(root, value);

    }

    void display()

    { inorderTraversal(root)

      ; cout << endl;

    }

    ~BinarySearchTree() {

        // Perform post-order traversal and delete nodes

        deleteTree(root);

    }

    void deleteTree(TreeNode* root) {

        if (root != nullptr)

            { deleteTree(root->

              >left); deleteTree(root->

              >right); delete root;

```

```

        }

    }

};

int main()

{ BinarySearchTree

bst; int choice,

value;

do {

Title: Implement Graph Traversal techniques: a) Depth First Search b) Breadth First Search

Theory: A Graph is a non-linear data structure which can have parent-child as well as other complex relationships between the nodes. It is a set of edges and vertices, where vertices are the nodes, and the edges are the links connecting the nodes. We can implement a graph using adjacency matrix or adjacency list.

Code:

```
// Graph Traversal techniques: a) Depth First Search b) Breadth First Search
```

```
#include <iostream>

#include <list>

using namespace std;

class Graph
{ private:

    int vertices;

    list<int>* adjList;

    void DFSUtil(int v, bool visited[]) {

        visited[v] = true;

        cout << v << " ";

        for (auto i = adjList[v].begin(); i !=
adjList[v].end(); ++i) {
```

```

        if (!visited[*i]) {

            DFSUtil(*i, visited);

        }

    }

}

public:

    Graph(int V) : vertices(V) {

        adjList = new list<int>[V];

    }

    void addEdge(int u, int v) {

        adjList[u].push_back(v);

    }

    void DFS(int start) {

        bool* visited = new bool[vertices];

        for (int i = 0; i < vertices; ++i) {

            visited[i] = false;

        }

        DFSUtil(start, visited);

    }

    void BFS(int start) {

```

```
bool* visited = new bool[vertices];

for (int i = 0; i < vertices; ++i) {

    visited[i] = false;

}

visited[start] = true;

cout << start << " ";

for (int i = 0; i < vertices; ++i) {

    if (!visited[i])

        { visited[i] =

            true; cout << i <<

              " ";

          }

}

for (int i = 0; i < vertices; ++i) {

    for (auto j = adjList[i].begin(); j !=
adjList[i].end(); ++j) {

        if (!visited[*j])

            { visited[*j] =

                true; cout << *j <<

                  " ";

            }

    }

}
```

```

        }

    }

    ~Graph() {

        delete[] adjList;

    }

};

int main() {

    int vertices, edges, start;

    cout << "Enter number of vertices: ";

    cin >> vertices;

    cout << "Enter number of edges: ";

    cin >> edges;

    Graph graph(vertices);

    cout << "Enter edges (u v):" << endl;

    for (int i = 0; i < edges; ++i) {

        int u, v;

        cin >> u >> v;

        graph.addEdge(u, v);

    }

    cout << "Enter starting vertex for traversal: ";

```

```
cin >> start;

cout << "Depth First Search (DFS): ";

graph.DFS(start);

cout << endl;

cout << "Breadth First Search (BFS): ";

graph.BFS(start);

cout << endl;

return 0;

}
```

Output: (screenshot)

Conclusion: Therefore, we can implement Graph Traversal techniques by Depth First and Breadth First using adjacency matrix.

Title: Implement Binary Search algorithm to search an element in the array.

Theory:

Binary Search is a searching algorithm which is used in a sorted array by repeatedly dividing the search interval in half. The idea of binary search is to use the information that the array is sorted and reduce the time complexity to $O(\log N)$.

Code:

```
// Binary Search algorithm to search an element in an array

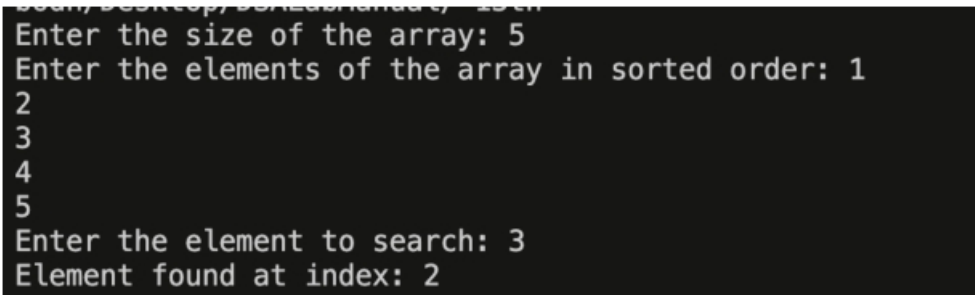

#include <iostream>
#include <algorithm>
using namespace std;

int binarySearch(int arr[], int left, int right, int target) {
    while (left <= right) {
        int mid = left + (right - left) / 2;
        if (arr[mid] == target)
            return mid;
        if (arr[mid] < target)
            left = mid + 1;
        else
            right = mid - 1;
    }
}
```

```
        return -1;
    }

int main() {
    int n;
    cout << "Enter the size of the array: ";
    cin >> n;
    int arr[n];
    cout << "Enter the elements of the array in sorted order: ";
    for (int i = 0; i < n; ++i) {
        cin >> arr[i];
    }
    int target;
    cout << "Enter the element to search: ";
    cin >> target;
    int index = binarySearch(arr, 0, n - 1, target);
    if (index != -1)
        cout << "Element found at index: " << index << endl;
    else
        cout << "Element not found in the array." << endl;
    return 0;
}
```

Output: (screenshot)

```
Enter the size of the array: 5
Enter the elements of the array in sorted order: 1
2
3
4
5
Enter the element to search: 3
Element found at index: 2
```

Conclusion: Therefore, we can implement Binary Search algorithm in a sorted array to search the index location of an element present in the array in an efficient manner.

Title: Implement Bubble Sort algorithm to sort elements of an array in ascending and descending order.

Theory:

In Bubble Sort algorithm, we traverse from left and compare adjacent elements and the higher one is placed at right side. In this way, the largest element is moved to the rightmost end at first. This process is then continued to find the second largest and place it and so on until the data is sorted.

Code:

```
// bubble sort algorithm to sort array in ascending and descending order

#include <iostream>

using namespace std;

void bubbleSortAscending(int arr[], int n) {

    for (int i = 0; i < n - 1; ++i) {

        for (int j = 0; j < n - i - 1; ++j) {

            if (arr[j] > arr[j + 1]) {

                // Swap arr[j] and arr[j+1]

                int temp = arr[j];

                arr[j] = arr[j + 1];

                arr[j + 1] = temp;

            }

        }

    }

}
```

```

}

void bubbleSortDescending(int arr[], int n) {
    for (int i = 0; i < n - 1; ++i) {
        for (int j = 0; j < n - i - 1; ++j) {
            if (arr[j] < arr[j + 1]) {
                // Swap arr[j] and arr[j+1]

                int temp = arr[j];
                arr[j] = arr[j + 1];
                arr[j + 1] = temp;
            }
        }
    }
}

int main() {
    int n;
    cout << "Enter the size of the array: ";
    cin >> n;

    int arr[n];
    cout << "Enter the elements of the array: ";
    for (int i = 0; i < n; ++i) {
        cin >> arr[i];
    }

    // Sort in ascending order

```

```
bubbleSortAscending(arr, n);

cout << "Sorted array in ascending order: ";

for (int i = 0; i < n; ++i) {

    cout << arr[i] << " ";

}

cout << endl;

// Sort in descending order

bubbleSortDescending(arr, n);

cout << "Sorted array in descending order: ";

for (int i = 0; i < n; ++i) {

    cout << arr[i] << " ";

}

cout << endl;

return 0;

}
```

Output: (screenshot)

```
000h/Desktop/DSALabManual/ 14th
Enter the size of the array: 6
Enter the elements of the array: 1
2
3
4
5
6
Sorted array in ascending order: 1 2 3 4 5 6
Sorted array in descending order: 6 5 4 3 2 1
```

Conclusion: Therefore, we can implement Bubble Sort algorithm to sort the array in ascending or descending order by traversing through the array and comparing the elements to the adjacent elements.
